Matrices

Properties of determinants:

- (i) If two rows or columns of matrix are identical, then the determinant is zero

$$\Delta = \begin{vmatrix} 0 & 1 & 2 \\ 1 & 2 & 3 \\ 0 & 1 & 2 \end{vmatrix} = 0$$

- (ii) If two rows or columns of matrix are interchanged then the sign of determinant changes.

$$\Delta = \begin{vmatrix} 1 & 2 \\ 1 & 2 & 3 \\ 3 & 1 & 1 \end{vmatrix} \quad -\Delta = \begin{vmatrix} 1 & 0 & 2 \\ 2 & 1 & 3 \\ 1 & 3 & 1 \end{vmatrix}$$

- (iii) If three rows or columns of matrix are interchanged then the sign of determinant is unaltered.

$$\therefore \Delta = \begin{vmatrix} 0 & 1 & 2 \\ 1 & 2 & 3 \\ 3 & 1 & 1 \end{vmatrix} = \begin{vmatrix} 1 & 2 & 3 \\ 3 & 1 & 1 \\ 0 & 1 & 2 \end{vmatrix}$$

- (iv) In the determinant of matrix if any column containing sum or difference of two elements then it can be split into sum or difference of two determinants.

$$\begin{vmatrix} a & a^2 & a^3 + 1 \\ b & b^2 & b^3 + 1 \\ c & c^2 & c^3 + 1 \end{vmatrix} = \begin{vmatrix} a & a^2 & a^3 \\ b & b^2 & b^3 \\ c & c^2 & c^3 \end{vmatrix} + \begin{vmatrix} a & a^2 & 1 \\ b & b^2 & 1 \\ c & c^2 & 1 \end{vmatrix}$$

$$A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

$$\Delta = ad - bc$$

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$$

Determinant of 3x3 matrix

$$\Delta = a_{11} \begin{bmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{bmatrix} - a_{12} \begin{bmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{bmatrix} + a_{13} \begin{bmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{bmatrix}$$

Operations for solving matrix are always less than one the order of matrix.

Upper and lower triangular matrix:

If all the elements above principal diagonal are zero then its said to be lower triangular matrix and if all elements below the principal diagonal are zero it is upper triangular matrix.

Lower triangular matrix =

$$\begin{bmatrix} 1 & 0 & 0 \\ 2 & 3 & 0 \\ 4 & 5 & 6 \end{bmatrix} = 18$$

Upper triangular matrix =

$$\begin{bmatrix} 1 & 2 & 3 \\ 0 & 4 & 5 \\ 0 & 0 & 6 \end{bmatrix} = 24$$

Note:-

If a matrix is either lower triangular or upper triangular determinant is product of principal diagonal elements.

Rank of matrix :-

If all minors of order $(r+1)$ are zero's, but there is at least one non-zero minor of order r , if exists, is called the Rank of the matrix and is indicated by $\rho(A)=r$. (5)

Eigen values and Eigen vectors:

Characteristic equation:

Let 'A' be the square matrix of order 'n x n'. I be the unit matrix of order 'n x n'. Then $|A - \lambda I| = 0$, is called the characteristic equation, where λ is a parameter.

The roots of characteristic equation are called the characteristic roots or Latent roots or Eigen values or proper values.

$$x = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix} \text{ or } [x_1 \ x_2 \ \dots \ x_n]^T$$

which satisfies the characteristic equation $[A - \lambda I]x = 0$ is called corresponding Eigen vector of the matrix.

$$[A - \lambda I] \cdot x = 0$$

Note:

(i) The sum of the eigen values of any matrix is equal to sum of the elements of its principal diagonal.

$$A = \begin{bmatrix} 1 & 1 & 3 \\ 1 & 5 & 1 \\ 3 & 1 & 1 \end{bmatrix}$$

$$\text{Trace of } A = 1 + 5 + 1$$

$$\text{Tr}(A) = 7 = (\text{sum of eigen values})$$

(ii) The product of Eigen values of any matrix is equal to its determinant.

are purely real.

$$S = \begin{bmatrix} 3 & 2 \\ 2 & 3 \end{bmatrix}$$

$$S^T = \begin{bmatrix} 3 & 2 \\ 2 & 3 \end{bmatrix}$$

(iv) The eigen values of skew symmetric matrix i.e.

- (b) 0, 1
- (c) 1, -1
- (d) i, -i

Ans: (d) i, -i are characteristic roots of matrix

(v) If the matrix is either lower triangular or upper triangular then principal diagonal elements are called the eigen values.

$$\begin{bmatrix} 1 & 2 & 3 \\ 0 & -4 & 1 \\ 0 & 0 & 5 \end{bmatrix}, \lambda = 1, -4, 5$$

(vii) After interchanging the rows or columns or after certain operations on matrix, if we obtain lower or upper triangular matrix, we may not necessarily get the values of eigen vector on principal diagonal.

$$\begin{bmatrix} 5-\lambda & 4 \\ 1 & 2-\lambda \end{bmatrix} = 0$$

$$\lambda^2 - 7\lambda + 6 = 0$$

According to theorem,

$$A^2 - 7A + 6I = 0$$

1-multiplicative identity.

Proof:-

A number L is said to be the limit of function $f(x)$ as $x \rightarrow a$, if for all $\epsilon > 0$ (however small) there exist $\delta > 0$ such that,

$$|f(x) - L| < \epsilon \quad \forall |x-a| < \delta$$

$$L-\epsilon < f(x) < L+\epsilon \quad \forall a-\delta < x < a+\delta$$

$$\lim_{x \rightarrow a} f(x) = L$$

Left limit:

$$\lim_{x \rightarrow a^-} f(x) = \lim_{h \rightarrow 0} f(a-h), \quad (a-\delta) < x < a$$

Right limit:

$$\lim_{x \rightarrow a^+} f(x) = \lim_{h \rightarrow 0} f(a+h), \quad a < x < a+\delta$$

Existence of limit

The limit of a function exist if both the left and right limit are existed and are equal

The continuity of a function:

A function $f(x)$ is said to be continuous at $x = a$

if

$$\lim_{x \rightarrow a} f(x) = f(a)$$

otherwise it is said to be a discontinuous function.

Types of discontinuous functions:

(i) Discontinuity of I-type (Jump discontinuity)

A function is said to have discontinuity of I-type

$$\boxed{\lim_{x \rightarrow a^-} f(x) \neq \lim_{x \rightarrow a^+} f(x)} \quad (\text{limit doesn't exist})$$

(ii) Discontinuity of II-type

A function is said to have discontinuity of II-type if either left limit or right limit or both does not exist.

(iii) Discontinuity of III-type (Removable discontinuity)

A function is said to have discontinuity of III-type

if

$$\lim_{x \rightarrow a^-} f(x) = \lim_{x \rightarrow a^+} f(x) \neq f(a)$$

Note-

$$\lim_{x \rightarrow a^-} f(x) = \lim_{x \rightarrow a^+} f(x) = \lim_{x \rightarrow a} f(x) \rightarrow \text{cont.}$$

Standard continuous functions:

- (i) x^n is continuous function $\forall x$, when $n > 0$ i.e. ($x, x^2, x^{2/3}, \dots$)
- (ii) x^n is continuous function $\forall x$, except $x=0$, when $n < 0$
- (iii) $|x|$ is continuous function $\forall x$.
- (iv) $\log x$ is continuous function $\forall x$ if $x > 0$
- (v) Every exponential function is continuous (e^x or a^x)
- (vi) $\sin x$ and $\cos x$ are continuous functions for all values of x .
- (vii) $\tan x$ and $\sec x$ are continuous functions $\forall x$, except $\cos x = 0$, i.e. except, $x = (2n-1) \cdot \frac{\pi}{2}$
- (viii) $\cot x$ and $\operatorname{cosec} x$ are continuous functions $\forall x$ except for $\sin x = 0$, i.e. $x = n\pi$
- (ix) Every algebraic function is continuous ($a_0 x^n + a_1 x^{n-1} + \dots + a_n$)
- (x) Every rational function $\left(\frac{f(x)}{g(x)}\right)$ is continuous except $g(x)=0$

$$\text{e.g. } f(x, y) = x^2 - xy + y^2$$

$$\begin{aligned} f(kx, ky) &= k^2 x^2 - k^2 xy + k^2 y^2 \\ &= k^2 (x^2 - xy + y^2) \end{aligned}$$

$$f(kx, ky) = k^2 (x, y)$$

Note:

- The product of two homogeneous functions is again a homogeneous functions.

$$f(x,y) = (x^3+y^3)(x^2-y^2)$$

$$n=3+2=5$$

(i) If function is in rational form, if both numerator and the denominator are homogenous functions then given function is also homogenous.

e.g.

$$f(x,y) = \frac{x^3+y^3}{x^2-y^2}$$

$$\text{degree, } n = 3-2 = 1$$

Euler's theorem:

If z is a homogenous function of degree n in x and y
then

$$x \cdot \frac{\partial z}{\partial x} + y \cdot \frac{\partial z}{\partial y} = n \cdot z$$

Note:

This formula is applicable directly if z is algebraic function.

e.g.

$$\text{If } z = (x^2+y^2)^{1/3}$$

$$x \cdot \frac{\partial z}{\partial x} + y \cdot \frac{\partial z}{\partial y} = \frac{2}{3} z \quad \therefore n = 2 \times \frac{1}{3} = \frac{2}{3}$$

$$\text{If } z = \frac{x^2y^2}{x^2+y^2}$$

$$x \cdot 2x + y \cdot 2y = 1 \cdot z \quad \therefore n = 2-1 = 1$$

$$\text{If } z = a_0 x^n + a_1 x^{n-1} y + a_2 x^{n-2} y^2 + \dots + a_n y^n$$

$$x \cdot \frac{\partial z}{\partial x} + y \cdot \frac{\partial z}{\partial y} = nz$$

Note:

If z is not algebraic and let $\phi(z)$ is algebraic and homogeneous of degree n in x and y then (34)

$$x \cdot \frac{\partial z}{\partial x} + y \cdot \frac{\partial z}{\partial y} = \frac{n \cdot \phi(z)}{\phi'(z)}$$

e.g. If $z = \log_e(x^2+y^2)$

$$e^z = x^2 + y^2$$

$$\therefore n = 2$$

$$x \cdot \frac{\partial z}{\partial x} + y \cdot \frac{\partial z}{\partial y} = \frac{2 \cdot e^z}{e^z} \quad \phi(z) = e^z$$
$$= 2$$

1. $z = \sin^{-1}\left(\frac{x^2+y^2}{x-y}\right)$

$$\sin z = \frac{x^2+y^2}{x-y}$$

$$n = (2-1) = 1$$

$$x \cdot \frac{\partial z}{\partial x} + y \cdot \frac{\partial z}{\partial y} = 1 \cdot \frac{\sin z}{\cos z}$$
$$= \tan z$$

2. $\therefore z = \tan^{-1}\left(\frac{x^3+y^3}{x-y}\right)$

$$\tan z = \frac{x^3+y^3}{x-y}$$

$$n = (3-1) = 2$$

$$x \cdot \frac{\partial z}{\partial x} + y \cdot \frac{\partial z}{\partial y} = 2 \cdot \frac{\tan z}{\sec^2 z}$$
$$= 2 \cdot \frac{\sin z}{\cos z} \cdot \frac{\cos^2 z}{1}$$
$$= 2 \sin z$$
$$= \sin 2z$$

$$3. z = x^2 \sin^{-1}\left(\frac{y}{x}\right) - y^2 \tan^{-1}\left(\frac{x}{y}\right)$$

Though it contains trigonometric functions for $(\frac{1}{2})$ & $(\frac{1}{2})$ the degree is zero $(j-1)=0$ and $(j-0)=0$.

Thus we consider there exist no inverse function.

$$x \frac{\partial z}{\partial x} + y \cdot \frac{\partial z}{\partial y} = 2z$$

$$4. z = (x^3 + y^3) e^{-xy}$$

$$n = 3 \quad \therefore \text{For } e^{-xy}, n = j - (j) \\ = 0$$

Application of Euler's theorem:

If z is homogenous function of degree n in x, y
then,

$$x^2 \cdot \frac{\partial^2 z}{\partial x^2} + 2xy \cdot \frac{\partial^2 z}{\partial x \cdot \partial y} + y^2 \cdot \frac{\partial^2 z}{\partial y^2} = n(n-1)z$$

This formula is applicable only when z is applicable

$$\text{e.g. If } z = (x^2 + y^2)^{\frac{1}{3}}$$

$$x^2 \cdot \frac{\partial^2 z}{\partial x^2} + 2xy \cdot \frac{\partial^2 z}{\partial x \cdot \partial y} + y^2 \cdot \frac{\partial^2 z}{\partial y^2} = \frac{2}{3} \left(\frac{2}{3} - 1 \right) \cdot z \\ = \frac{2}{3} \left(-\frac{1}{3} \right) \cdot z \\ = -\frac{2}{9} z$$

$$\text{If } z = \frac{xy}{x+y}$$

$$\therefore n = (j+j) - j = 1$$

$$x^2 \cdot \frac{\partial^2 z}{\partial x^2} + 2xy \cdot \frac{\partial^2 z}{\partial x \cdot \partial y} + y^2 \cdot \frac{\partial^2 z}{\partial y^2} = 1(1-1) \cdot z \\ = 0$$

If $z = \tan^{-1} \left(\frac{x^2+y^2}{x-y} \right)$

(35)

$$\tan z = \frac{x^2+y^2}{x-y}$$

$$x \cdot \frac{\partial z}{\partial x} + y \cdot \frac{\partial z}{\partial y} = x \cdot \frac{\tan z}{\tan^2 z} \\ = \sin 2z$$

$$x \cdot \frac{\partial^2 z}{\partial x^2} + \frac{\partial z}{\partial x} (1) + y \cdot \frac{\partial^2 z}{\partial x \cdot \partial y} = 2 \cos 2z \cdot \frac{\partial z}{\partial x}$$

$$x \cdot \frac{\partial^2 z}{\partial x^2} + y \cdot \frac{\partial^2 z}{\partial x \cdot \partial y} = (-1 + 2 \cos 2z) \cdot \frac{\partial z}{\partial x}$$

$$x^2 \cdot \frac{\partial^2 z}{\partial x^2} + xy \cdot \frac{\partial^2 z}{\partial x \cdot \partial y} = (2 \cos 2z - 1) \cdot x \cdot \frac{\partial z}{\partial x} \quad \text{--- a}$$

Similarly

$$y^2 \cdot \frac{\partial^2 z}{\partial y^2} + xy \cdot \frac{\partial^2 z}{\partial x \cdot \partial y} = (2 \cos 2z - 1) \cdot y \cdot \frac{\partial z}{\partial y} \quad \text{--- b}$$

Adding --- a & --- b

$$x^2 \cdot \frac{\partial^2 z}{\partial x^2} + 2xy \cdot \frac{\partial^2 z}{\partial x \cdot \partial y} + y^2 \cdot \frac{\partial^2 z}{\partial y^2} = (2 \cos 2z - 1) \cdot \sin 2z \\ = \sin 4z - \sin 2z$$

* Explicit function:

Any function which we can express in the form of either $y = f(x)$ or $x = g(y)$ etc. is called an explicit function.

e.g. If

$$y = ax^2 + bx + c$$

$$\frac{dy}{dx} = 2ax + b$$

$$\frac{d^2y}{dx^2} = 2a$$

$$\frac{d^3y}{dx^3} = 0$$

Implicit function:

Any function which is not explicit is said to be an implicit function.

$$\text{e.g. } ax^2 + 2hxy + by^2 = 0$$

$$\therefore a \cdot 2x + 2h \left[x \cdot \frac{dy}{dx} + y \right] + 2by \cdot \frac{dy}{dx} = 0$$

$$(ah+by) \cdot \frac{dy}{dx} = -ax + hy$$

$$\boxed{\frac{dy}{dx} = \frac{-ax + hy}{(ah+by)}}$$

$$\frac{d^2y}{dx^2} = \dots \quad (\text{complicated & lengthy})$$

Partial derivatives are easier & simpler than ordinary derivatives because we treat y as constant while differentiating given function w.r.t. x & x as constant while differentiating given function w.r.t. y .

$$z = f(x, y)$$

~~Remember~~

$$p = \frac{\partial z}{\partial x}, \quad q = \frac{\partial z}{\partial y}, \quad r = \frac{\partial^2 z}{\partial x^2}$$

$$s = \frac{\partial^2 z}{\partial x \cdot \partial y}, \quad t = \frac{\partial^2 z}{\partial y^2}$$

$$\frac{\partial^2 y}{\partial x^2} = \frac{-[q^2r - 2pq s + p^2t]}{q^3}$$

(for implicit function)

$$ax^2 + 2hxy + by^2 = 1$$

(particular formula)

$$\boxed{\frac{dy}{dx^2} = \frac{h^2 - ab}{(hx+by)^3}}$$

$$1. \underline{2x^2 + 4xy + 3y^2 = 1}$$

$$a=2, b=3, h=\frac{4}{2}=2$$

$$\begin{aligned}\frac{d^2y}{dx^2} &= \frac{h^2-ab}{(bx+by)^3} \\ &= \frac{4-6}{(2x+3y)^3} \\ &= \frac{-2}{(2x+3y)^3}\end{aligned}$$

$$2x^2 + 4xy + 3y^2 = 1$$

$$ax^2 + 2hxy + by^2 = 1$$

$$a=2, b=3, h=\frac{4}{2}=2$$

$$h=2$$

$$b=3$$

$$2. x^2 + 2xy + y^2 = 1$$

$$a=1, b=1, h=\frac{1}{2}$$

$$\begin{aligned}\frac{d^2y}{dx^2} &= \frac{\frac{1}{4}-1}{(-\frac{1}{2}x+y)^3} \\ &= \frac{-\frac{3}{4}}{(\frac{x+4}{2})^3} \\ &= \frac{-2 \times 3}{(x+y)^3} \\ &= \frac{-6}{(x+y)^3}\end{aligned}$$

If given function is in the form $f = g = 0$ or $c = 0$

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = \text{const}$$

then

$$\boxed{\frac{d^2y}{dx^2} = \frac{abc + 2fgh - af^2 - bg^2 - ch^2}{(bx+by+f)^3}}$$

- (standard formula)

(Applicable for all forms above)

$$2x^2 + 4xy + 3y^2 + 2x + 4y + 1 = 0$$

$$a=2, b=3, c=1, h=\frac{4}{2}=2, g=\frac{2}{2}=1, f=\frac{4}{2}=2$$

$$\frac{d^2y}{dx^2} = \frac{abc + 2fgh - af^2 - bg^2 - ch^2}{(chx + by + f)^3}$$

$$= \frac{6 + 8 - 8 - 3 - 4}{(2x+3y+2)^3}$$

$$= \frac{-1}{(2x+3y+2)^3}$$

1. $y^2 - 5x + 4x^2 = 8$ find $\frac{dy}{dx^2} = ?$

$$4x^2 - 5x - y^2 - 8 = 0$$

$$\therefore a=4, b=-1, h=0, g=(-\frac{5}{2}), f=0, c=-8.$$

$$\frac{d^2y}{dx^2} = \frac{32 + 0 - 0 + (-1)\frac{25}{4} - 0}{(0 - 1 \cdot y + 0)^3}$$

$$= \frac{32 - \frac{25}{4}}{-y^3}$$

$$= \frac{-153}{4y^3}$$

2. $y^2 - 5x + 4x^2 = 8$ find $\frac{d^2y}{dx^2}$

$$y^2 - 5x + 4x^2 = 8 \quad (\text{explicit function})$$

$$a=4, b=1, g=(-\frac{5}{2}), c=0, h=0, f=0$$

$$\frac{d^2y}{dx^2} = \frac{0 + 0 - 0 - \frac{25}{4} - 0}{(0 + y + 0)^3}$$

$$= \frac{-25}{4y^3}$$

Composite function \rightarrow

Any function in function is said to be composite function.

If z is function in x and y and x, y are functions in ' t ' then z is called a composite function in ' t '.

Total derivative of composite function:

If $z = f(x, y)$, $x = g(t)$ & $y = h(t)$ then total derivative of z w.r.t. t is denoted by $\frac{dz}{dt}$ and is given by

$$\frac{dz}{dt} = \frac{\partial z}{\partial x} \cdot \frac{dx}{dt} + \frac{\partial z}{\partial y} \cdot \frac{dy}{dt}.$$

If $u = f(x, y, z)$ & (x, y, z) are function of t

$$\frac{du}{dt} = \frac{\partial u}{\partial x} \cdot \frac{dx}{dt} + \frac{\partial u}{\partial y} \cdot \frac{dy}{dt} + \frac{\partial u}{\partial z} \cdot \frac{dz}{dt}$$

If $z = e^x \cdot \sin y$, $x = \log t$, $y = t^2$.

$$= t^5 \cdot t$$

$$= t^6$$

$$\left(\frac{du}{dt} \right)_{t=2} = 6 \cdot t^5 = 6 \times (2)^5 = 6 \times 32 = 192$$

Maxima and Minima :

Maximum value:

If a continuous function $f(x)$ increases to a certain value and then decreases, that value is called maximum value of a function.

Minimum value:

If a continuous function $f(x)$ decreases to a certain value and then increases that value is called minimum value of the function.

- (i) The maxima or minima occurs alternatively.
- (ii) A function can have several maximum and several minimum values.
- (iii) The minimum value may be greater than maximum value.
- (iv) The least minimum value is called global minimum or universal minimum and highest maximum value is called a global maximum or universal maximum.

For a function $f(x)$, for maxima or minima,

$$f'(x) = 0$$

$$x = \alpha, \beta, \gamma, \dots$$

For $x = \alpha$, if $f''(\alpha) > 0$ the $f(x)$ is minimum at α .

Minimum value = $f(\alpha)$

(40)

For $x = \beta$, if $f''(\beta) < 0$, the $f(x)$ is maximum at β .

Maximum value = $f(\beta)$

for $x = \gamma$, if $f''(\gamma) = 0$, the $f(x)$ is stationary.

If $f'''(\gamma) \neq 0$, then γ is said to be inflection point

For a maxima or minima. Let $p=0$ and $q=0$ since p and q are functions in x and y , so we have two equations in x and y . Solve these equations and get relation between x and y .

e.g. ($x=y$, $x=-y$, $x=2y$ etc.)

Put this relation either in $p=0$ or in $q=0$, then the equation transformed to either purely in x or in y . solve the equation and get the roots

$$x = x_0, x_1, -x_2 \dots$$

$$y = y_0, y_1, y_2 \dots$$

$(x_0, y_0), (x_1, y_1), (x_2, y_2) \dots$ are called stationary points or critical points (points at which maxima, minima can be decided)

Take point (x_0, y_0) and find values of r , s and t .

Case I \rightarrow

Minimum value = $f(x_0, y_0)$

Case II \rightarrow

Case IV :

Gradient of scalar function :

Let $\phi(x, y, z) = c$ be any scalar function then the gradient of ϕ is denoted by $\text{grad } \phi$ or $\nabla \phi$ and is defined as

$$\text{grad } \phi = i \frac{\partial \phi}{\partial x} + j \frac{\partial \phi}{\partial y} + k \frac{\partial \phi}{\partial z}$$

We know that,

$$\vec{r} = xi + yj + zk$$

$$r = |\vec{r}| = \sqrt{x^2 + y^2 + z^2}$$

$$r^2 = x^2 + y^2 + z^2$$

$$2r \cdot \frac{\partial r}{\partial x} = 2x$$

$$\frac{\partial r}{\partial x} = \frac{x}{r}$$

similarly,

$$\frac{\partial r}{\partial y} = \frac{y}{r} \quad \& \quad \frac{\partial r}{\partial z} = \frac{z}{r}$$

$$\begin{aligned}\text{grad } r &= \nabla \cdot r = i \frac{\partial r}{\partial x} + j \frac{\partial r}{\partial y} + k \frac{\partial r}{\partial z} \\ &= i \left(\frac{x}{r} \right) + j \left(\frac{y}{r} \right) + k \left(\frac{z}{r} \right) \\ &= \frac{xi + yj + zk}{r} \\ &= \frac{\vec{r}}{r}\end{aligned}$$

$$\text{grad } r = \nabla r = \frac{\vec{r}}{r}$$

Tangent vector to a curve:

Let $\vec{r}(t)$ be the given vector curve then $\frac{d\vec{r}}{dt}$ is called the tangent vector to the given curve.

$$\vec{r} = xi + yj + zk$$

$$\frac{d\vec{r}}{dt} = \frac{dx}{dt} i + \frac{dy}{dt} j + \frac{dz}{dt} k.$$

Normal to a surface:

Let $\phi(x, y, z) = c$ be any surface, the $\nabla(\phi)$ is called normal to the surface ϕ . and $\frac{\nabla \phi}{|\nabla \phi|}$ is unit normal vector to the surface ϕ . and is denoted by N .

$$N = \frac{\nabla \phi}{|\nabla \phi|}$$

Directional derivative:

Let $\phi(x, y, z) = c$ be any surface, then directional derivative of ϕ is defined by $\nabla \phi \cdot e$ where e is the unit vector in the direction of given vector.

If given vector is a

$$e = \frac{\vec{a}}{|\vec{a}|}$$

directional derivative = $\nabla \phi \cdot e$

The max. or greatest value of directional derivative or magnitude of directional derivative of a scalar function ϕ is defined by $|\nabla \phi|$.

For tangent ①

$$a = a_1 i + a_2 j + a_3 k$$

For tangent ②

$$b = b_1 i + b_2 j + b_3 k$$

$$\cos \theta = \frac{a \cdot b}{|a||b|}$$

where,

$$a \cdot b = a_1 b_1 + a_2 b_2 + a_3 b_3$$

Note:

The two curves cut each other orthogonally ($\theta = 90^\circ$)

$$a \cdot b = 0$$

Angle between two surfaces:-

The angle between the two surfaces is the angle between the normals drawn at their point of intersection.
If f and g are any two surfaces and θ is angle between them,

$$\cos \theta = \frac{\nabla f \cdot \nabla g}{|\nabla f| |\nabla g|}$$

Note:

If the two surfaces cut each other orthogonally, then

$$\nabla f \cdot \nabla g = 0$$

(A) Non-homogeneous equation:

The D.E. is of form $\frac{dy}{dx} = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$ is said to be a non-homogeneous differential equation.

because of
constants H
equ' is not
homogeneous

Case I: If $a_1 b_2 - a_2 b_1 \neq 0$ then,

substitute $x = X + h, y = Y + k$.

where h and k are constants to be determined.

Case II: If $a_1 b_2 - a_2 b_1 = 0$ then, some part of numerator and denominator which is equal, is considered as substitution.

Find the substitution that transforms the given D.F. from non-homogeneous to homogeneous form.

$$\frac{dy}{dx} = \frac{3x+y-5}{2x+2y-2}$$

$$6-2 \neq 0$$

Case I :

h	k	1	h
3	1	-5	3
2	2	-2	2

$$\frac{h}{-2+10} = \frac{k}{-10+6} = \frac{1}{6-2}$$

$$\frac{h}{8} = \frac{k}{-4} = \frac{1}{4}$$

$$h = \frac{8}{4} = 2$$

$$k = \frac{-4}{4} = -1$$

$$x = X + 2$$

$$y = Y - 1$$

$$\frac{dy}{dx} = \frac{x+2y-3}{2x+y+3}$$

$$\begin{matrix} h & k & 1 & h \\ 1 & 2 & -3 & 1 \\ 2 & 1 & -3 & 2 \end{matrix}$$

$$\frac{h}{-6+3} = \frac{k}{-6+3} = \frac{1}{1-4}$$

$$\frac{h}{-3} = \frac{k}{-3} = \frac{1}{-5}$$

$$\therefore h = k = 1$$

$$x = X + 1$$

$$y = Y + 1$$

$$\frac{dy}{dx} = \frac{x+2y+1}{2x+4y+1}$$

$$4 - 2(2) = 0$$

$$\frac{dy}{dx} = \frac{(x+2y)+1}{2(x+2y)+1}$$

∴ substitute $(x+2y) = z$.

$$\frac{dy}{dx} = \frac{x+2y+3}{2x+y+5}$$

(8)

$x - 4 \neq 0$

h	k	j	h
1	2	3	1
2	1	5	2

$$\frac{h}{10-3} = \frac{k}{6-5} = \frac{1}{1-4}$$

$$\frac{h}{7} = \frac{k}{1} = \frac{1}{-3}$$

$$h = \frac{-7}{3} \quad k = \frac{-1}{3}$$

$$x = X + \frac{7}{3}$$

$$y = Y - \frac{1}{3}$$

$$\int 2xy \cdot dx + \int y^2 \cdot dy = c$$

$$x^2y + \frac{y^3}{3} = c$$

shortcut :

$$(ax + by + g)dx + (bx + by + f)dy = 0$$

$$\frac{\partial M}{\partial y} = b$$

$$\frac{\partial M}{\partial x} = b$$

\therefore solution is

$$\therefore \int e^x \cdot \tan y \cdot dx + \int \sec^2 y \cdot dy = c$$

Method 2

If $Mdx + Ndy = 0$ is non-exact but homogenous and

The necessary and sufficient condition for a function $f(z) = u(x, y) + i \cdot v(x, y)$ to be analytic is, it should satisfy Cauchy-Riemann's (C-R) equation as.

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}$$

$$\frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}$$

Harmomic function:

Any function of x and y satisfying the Laplace's equation is said to be harmonic function.

Numerical methods

Solution of non-linear equations :

Let $f(x) = 0$ be any non-linear equation. To find the approximate root of $f(x) = 0$, choose any two values of $x = a, b$ particularly adjacent values in such a way that there functional values must have opposite signs. Then we must say that root lies between a and b . This approximate root can be found by

- (i) Method of bisection
- (ii) Regula-falsi method
- (iii) Newton-Raphson method

(i) Method of bisection

$$\begin{array}{r} \text{AT 2004} \\ \text{AT 180848} \end{array}$$

if $f(x_1) < 0$

$$f(a) \cdot f(x_1) \cdot f(b)$$

$$x_2 = \frac{x_1 + b}{2}$$

$$f(x_2) > 0$$

$$x_3 = \frac{x_1 + x_2}{2}$$

(must go upto 13th to 14th approximation)

The rate of convergence in bisection method is very slow. Comparatively bisection method, the Regula-falsi method has little fast rate of convergence.

(ii) Regula-falsi method :

$$x_1 = \frac{a f(b) - b f(a)}{f(b) - f(a)}$$

(must go upto 7th to 8th approximation)

(i) Newton-Raphson method:

It has very fast rate of convergence. The convergence of Newton-Raphson method is quadratic convergence or the 2nd order convergence.

$$x_1 = x_0 - \frac{f(x_0)}{f'(x_0)}$$

4. $f(x) = x^2 - 2x - 1$, $x_0 = 2$, $x_1 = ?$

$$\begin{aligned} x_1 &= 2 - \frac{(2)^2 - 2(2) - 1}{2(2) - 2} \\ &= 2 - \frac{-1}{2} \\ &= \frac{5}{2} = 2.5 \end{aligned}$$

$$\begin{aligned} x_2 &= 2.5 - \frac{(2.5)^2 - 2(2.5) - 1}{2(2.5) - 2} \\ &= 2.5 - \frac{6.25 - 5 - 1}{5 - 2} \\ &= 2.5 - \frac{0.25}{3} \\ &= \frac{7.25}{3} = 2.417 \end{aligned}$$
